ABSTRACT

This project implements a simple IoT-based irrigation assistant that measures soil moisture and ambient temperature–humidity using an ESP32 connected to a capacitive soil moisture sensor and a DHT11/DHT22 sensor, with real-time visualization and control through the Blynk mobile dashboard over Wi-Fi. Continuous monitoring and cloud-connected dashboards make irrigation decisions timely and data-driven, reducing over-watering and labor while improving plant health and water efficiency. The design leverages widely available components and straightforward interfacing on the ESP32 platform, including standard soil moisture sensor wiring and DHT11 temperature–humidity acquisition, to keep cost and complexity low. Demonstrated workflows and tutorials confirm feasibility of live gauges, push notifications, and threshold logic within the Blynk ecosystem for garden or potted-plant scenarios.

KEYWORDS

IoT, ESP32, Soil Moisture Sensor, DHT11/DHT22, Blynk, Smart Irrigation, Wi-Fi, Relay Control, Mobile Dashboard.

1. Introduction

1.1 Problem Statement

Manual irrigation often leads to inconsistent watering, water wastage, and poor plant outcomes due to a lack of real-time insights into soil moisture and microclimate conditions at the plant root zone.

There is a need for a low-cost, connected solution that monitors soil moisture and environmental parameters, notifies the user at the right time, and optionally actuates a pump or provides an easy remote control path through a phone-based interface.

1.2 Objective's

- Measure soil moisture, temperature, and humidity in real time using ESP32 with a soil moisture sensor and DHT11/DHT22, updating a mobile dashboard at short intervals.
- Provide a Blynk-based interface with gauges for moisture, temperature, and humidity, plus optional notifications for low moisture events.
- Support reliable ESP32–sensor interfacing and stable Wi-Fi connectivity to ensure responsive telemetry and control with minimal downtime.
- Reduce water waste and labor by making irrigation decisions data-driven, improving efficiency and plant health in small garden deployments.
- Keep the bill of materials low and use widely documented workflows to simplify replication and maintenance for students and hobbyists.
- Ensure the design can be extended with features such as data logging, refined thresholds, or weather-informed logic as future scope.

2. System Architecture

The core system is an IoT-enabled smart irrigation unit, using an ESP32 microcontroller as its brain. The architecture consists of three major layers: sensing, processing and actuation, and cloud/mobile communication.

2.1 Sensing Layer

2.1.1 Capacitive Soil Moisture Sensor:

- Continuously measures the volumetric water content in the soil, providing a real-time analog value proportional to soil wetness.

2.1.2 Temperature and Humidity Sensor (DHT11 or DHT22):

- Monitors the local environment to provide temperature (°C) and relative humidity (%) data.

2.2 Processing and Actuation Layer

2.2.1 ESP32 Microcontroller:

- Reads analog/digital data from the soil moisture sensor and DHT11/DHT22 sensor at set intervals (e.g., every 1-5 seconds).
- Compares sensor data against calibrated thresholds (e.g., soil moisture < 40%).
- Connects to local Wi-Fi and coordinates data exchange with the Blynk IoT cloud.

2.3 Communication and User Interface Layer

2.3.1 Wi-Fi Connectivity:

- Enables the ESP32 to send real-time sensor data and receive remote instructions via the internet.

2.3.2 Blynk IoT Cloud Platform:

- Dashboard displays live readings for soil moisture, temperature, and humidity using virtual pins and widgets (e.g., gauges).
- Push notification/alert system triggers when soil is too dry.
- Manual control button on the dashboard allows the user to override and turn ON/OFF the pump or indicator remotely.

2.3.3 Mobile App (Blynk Dashboard):

- Provides end-users with a friendly interface for monitoring and control, accessible from anywhere.

2.3.4 Data Flow and Actions:

1. Sensors continuously sample soil/environmental conditions.
2. ESP32 reads sensor values, processes them, and decides: “No watering needed” OR “Water now”.
3. ESP32 updates the Blynk cloud and triggers local actuators as determined by logic.
4. Blynk platform reflects live readings, triggers notifications if thresholds are breached, and allows manual override.

2.3.5 Power Management

- The system can be powered by a USB adapter, Li-ion batteries, or a solar panel for remote or outdoor deployments. The ESP32, sensors, and actuators should be matched to a suitable voltage supply, typically 3.3V or 5V.

---

3)Technology Overview

This section explains the main hardware and software components powering the IoT irrigation assistant, highlighting their features and roles.

3.1 ESP32

3.1.1 Definition:

The ESP32 is a low-cost, highly integrated microcontroller with built-in Wi-Fi and Bluetooth, designed for IoT applications, sensor interfacing, and real-time data processing.

3.1.2 Key Features:

- Dual-core 32-bit processor (up to 240 MHz)
- 520 KB SRAM and typical 4 MB Flash memory
- Integrated Wi-Fi (802.11 b/g/n) and Bluetooth v4.2
- 34 programmable GPIO pins for versatile interfacing
- Built-in ADC/DAC, UART, SPI, I2C, PWM, capacitive touch, and more
- Secure boot, hardware encryption, cryptographic accelerators
- Operates at 2.7V–3.6V with various low-power modes
- Supports both real-time control and deep sleep for energy savings

3.1.3 Why is it used?

The ESP32 is used for its reliable, real-time wireless communication ability (Wi-Fi/Bluetooth), processing power to handle sensor data, compatibility with IoT platforms like Blynk, and its extensive GPIOs for connecting multiple sensors and actuators—all at a low cost.

3.2) Soil Moisture Sensor

3.2.1 Definition:

A soil moisture sensor measures the volumetric content of water in soil by detecting electrical resistance or capacitance, outputting an analog or digital signal.

3.2.2 Key Features:

- Measures water content in soil (analog output)
- Capacitive or resistive sensing types are common
- Simple 2- or 3-wire interface (VCC, GND, Analog Out)
- Operates at 3.3V–5V supply voltage
- Outputs voltage that varies with soil moisture level
- Compact and easy to embed in plants

3.2.3 Why is it used?

It provides real-time, low-cost monitoring of soil water content, enabling data-driven irrigation decisions and protecting plants from both over- and under-watering.

3.3) DHT11 Sensor

3.3.1 Definition:

The DHT11 is a basic digital temperature and humidity sensor, widely used in environmental monitoring projects.

3.3.2 Key Features:

- Digital temperature and humidity measurement
- Detects 0–50°C temperature and 20–80% relative humidity
- ±2°C temperature accuracy and ±5% humidity accuracy
- Single-wire digital data output for easy connection
- Powered by 3V–5V, low power and cost

3.3.3 Why is it used?

It is simple, affordable, and provides reliable environmental data for assessing both plant comfort and microclimate trends, helping optimize irrigation routines.

3.4) Blynk IoT Platform

3.4.1 Definition:

Blynk is an IoT platform that allows seamless interaction between hardware and mobile devices, enabling live data display, notifications, and device control via Wi-Fi/internet.

3.4.2 Key Features:

- Mobile-controlled dashboards with gauges, buttons, and notifications
- Real-time data visualization and device control
- Uses virtual pins for easy sensor/widget linkage
- Cloud connectivity for remote access and alerts
- Simplifies IoT development for ESP32 and similar boards

3.4.3 Why is it used?

Blynk accelerates IoT development by providing instantly customizable mobile dashboards and straightforward cloud/device integration, making remote monitoring and control accessible for all users.

3.5) Arduino IDE

3.5.1 Definition:

The Arduino IDE is a popular open-source development environment for writing, compiling, and uploading code to microcontroller boards like the ESP32.

3.5.2 Key Features:

- Popular development environment for microcontrollers
- Supports ESP32 and many other boards
- Simplified C++/Wiring code syntax
- Serial monitor for debugging and feedback
- Extensive library and community support for sensors/devices
- Runs on Windows, macOS, and Linux platforms

3.5.3 Why is it used?

It simplifies embedded coding for beginners and experts alike, offering fast prototyping, wide library support (including Blynk and sensor drivers), and seamless integration with ESP32 boards.

---

4. List of Materials

COMPONENT	QUANTITY	NOTES	PRICE
ESP32	1	Microcontroller, system core	₹350
Soil Moisture Sensor	1	Detects soil water level	₹75
DHT11 Sensor	1	Measures temp & humidity	₹75
Blynk IoT	-	Cloud dashboard/alerts	Free (Trial)
Jumper Wires	Required	Connections/components	₹40
Soil and Water	Required	Plant with medium for test	Negligible

5) Working Methodology

The soil moisture monitoring system operates in a continuous cycle with the following step-by-step execution flow:

5.1 Sensor Data Acquisition:

The capacitive soil moisture sensor is embedded in the plant soil and connected to the ESP32's analog input pin. It continuously measures the volumetric water content by generating an analog voltage proportional to moisture levels. Simultaneously, the DHT11 sensor measures ambient temperature and humidity via a digital pin.

5.2 Analog-to-Digital Conversion:

The ESP32 reads the analog output from the soil moisture sensor using its built-in ADC (Analog-to-Digital Converter) to convert the raw voltage signal into a numerical percentage representing soil moisture. The digital temperature and humidity data from the DHT11 are also acquired.

5.3 Data Processing and Threshold Comparison:

The microcontroller compares the soil moisture value to a calibrated threshold (example: 40%). If the value is below the threshold, the soil is considered dry; otherwise, it is sufficiently moist.

5.4 Data Transmission and Visualization:

The ESP32 transmits real-time data (soil moisture %, temperature, humidity) to the Blynk cloud server over Wi-Fi. The Blynk app updates its gauges and notification widgets every few seconds to keep the user informed.

5.5 User Interaction:

The user can manually override the automation via the Blynk dashboard, switching the water pump ON or OFF using a virtual button, ensuring flexible control.

5.6 Iteration:

The cycle repeats indefinitely, keeping the system responsive to environmental changes for timely irrigation decisions.

This method ensures intelligent water management, enhances plant health, and reduces manual labor and water waste by leveraging continuous sensing, wireless telemetry, and user-friendly mobile control.

---

6) Software and Code Overview

6.1 Functionality

The software running on the ESP32 continuously reads analog data from the soil moisture sensor and digital temperature/humidity data from the DHT11 sensor. It processes these sensor readings, converts the soil moisture reading to a meaningful percentage, and sends all data to the Blynk IoT platform over Wi-Fi. When the soil moisture falls below a predefined threshold, the code triggers alerts and can actuate an LED or relay for watering. The Blynk dashboard on the user's mobile device displays real-time live data and allows manual control of the pump or indicator.

  Blynk.virtualWrite(V2, h);
```

```
  Serial.print("Soil Moisture : ");
  Serial.print(soilmoisturepercentage);
  Serial.print(" Temperature : ");
  Serial.print(t);
  Serial.print("    Humidity : ");
  Serial.println(h);
}

void setup()
{
  Serial.begin(115200);
  Blynk.begin(auth, ssid, pass);
  dht.begin();
  timer.setInterval(100L, sendSensor);
}

void loop()
{
  Blynk.run();
  timer.run();
}
```

6.3 Key Code Features

- Reads soil moisture sensor analog input and maps raw ADC values to percentage.
- Reads temperature and humidity from DHT11 sensor.
- Periodically sends data to Blynk virtual pins for live dashboard display.
- Prints sensor values to Serial Monitor for debugging.
- Sets Wi-Fi credentials and Blynk authentication to connect ESP32 to Blynk cloud.
- Uses timer to schedule regular sensor data updates every 100 milliseconds.
- Supports real-time monitoring and control through Blynk app via Wi-Fi.

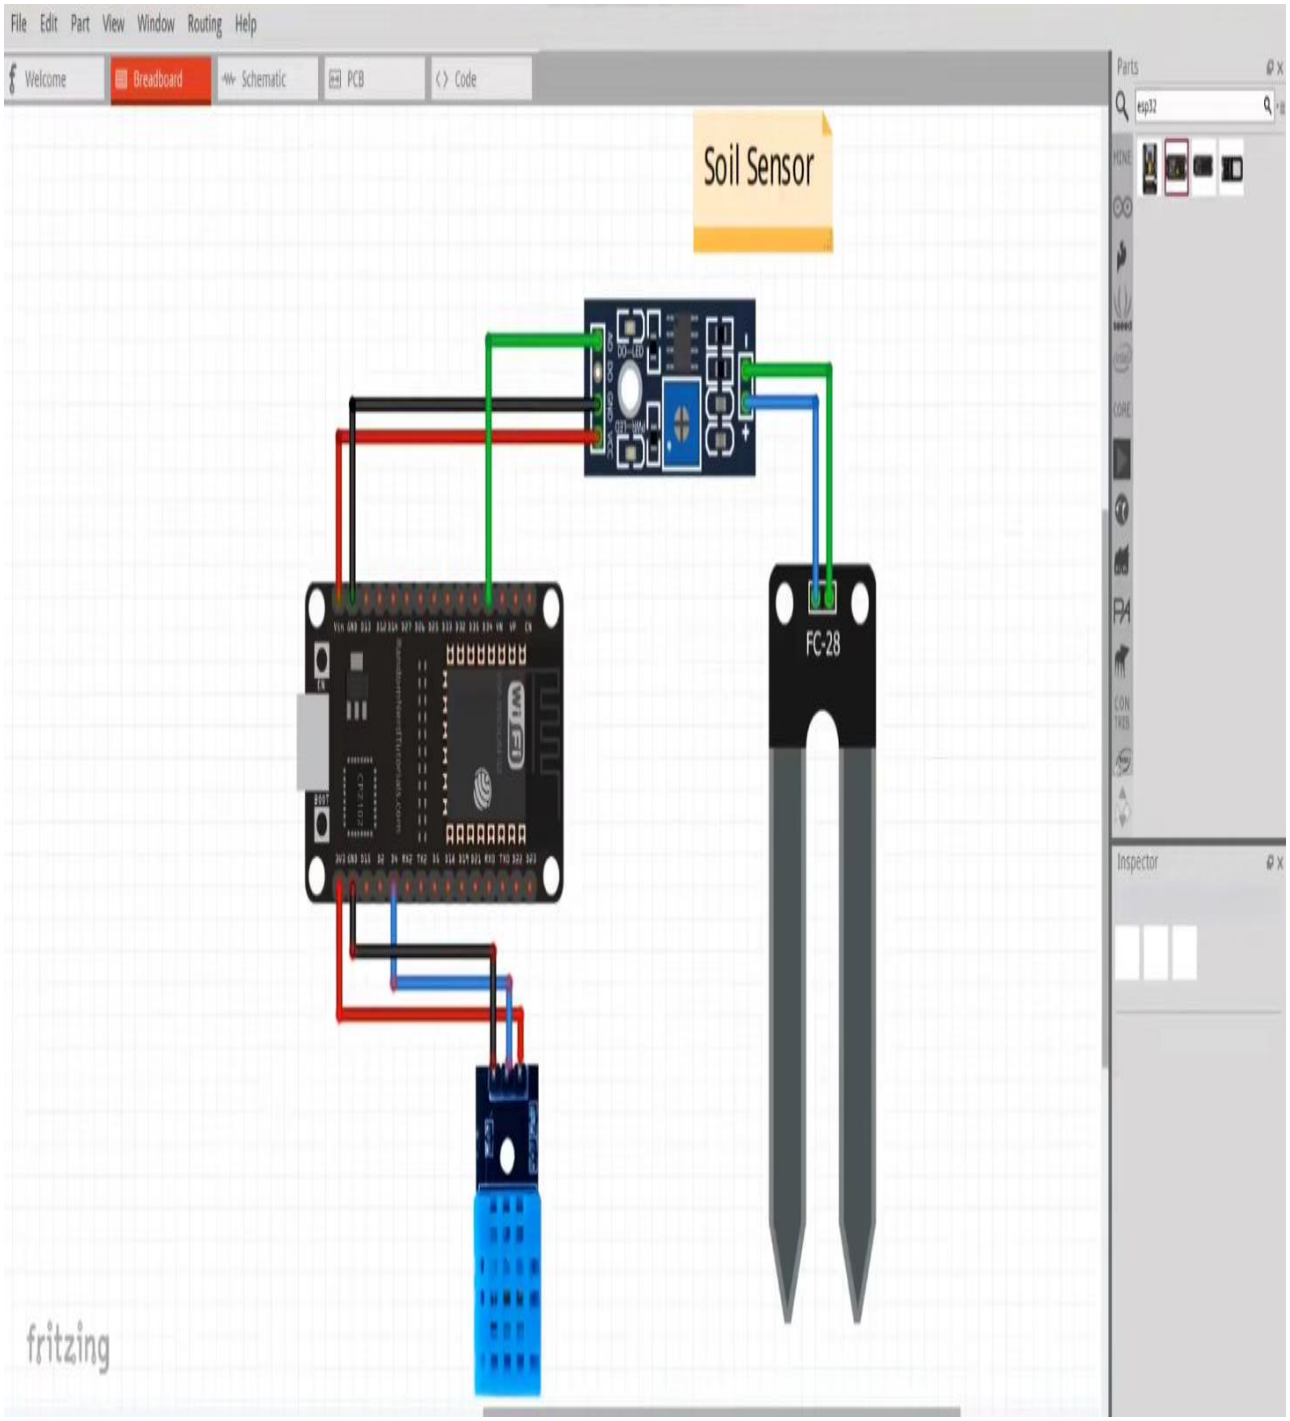
6.4 This Code Does

- Continuously monitors soil moisture and environmental conditions.
- Translates raw sensor data into meaningful metrics.
- Provides seamless integration with the Blynk IoT mobile platform.
- Alerts users when soil moisture is low and enables remote pump/LED control.
- Forms the backbone software logic for your IoT-based irrigation assistant.

This software design is compact, efficient, and suitable for scaling with additional sensors or actuators in the future.

---

7) Hardware Schematic Connection:



8) Testing and Validation

8.1 Objective of Testing and Validation

The objective of testing and validation is to ensure the IoT-based soil moisture monitoring system reliably and accurately detects soil moisture levels and environmental conditions, triggers alerts correctly, and interfaces smoothly with the Blynk app for real-time monitoring and control. This ensures the system's practical usability for automatic or assisted irrigation, minimizing water waste and enhancing plant care.

8.2 Testing Conditions

- Soil moisture sensor inserted into dry soil, moist soil, and submerged in water for calibration.
- Environmental temperature and humidity were measured at room temperature, under varying humidity conditions.
- Wi-Fi connectivity tested for data transmission reliability.
- Blynk app observed for timely data updates and alert notifications.
- LED/relay output tested for correct actuation below threshold moisture levels.

8.3 Tests Conducted

TEST	DESCRIPTION	RESULTS
Soil Moisture Response	Sensor readings tested across dry to wet soil	Accurate moisture % readings from 0-100% detected
Temperature & Humidity	DHT11 sensor validated at varying conditions	Data matched expected readings within ±2°C, ±5% RH errors
Wi-Fi Stability	ESP32 connection maintained during operation	Consistent data upload, no dropouts
Blynk Dashboard	Real-time display of sensor data on mobile app	Rapid updates and alert notifications worked as intended
Actuation Control	LED and relay activated/deactivated on commands	Timely and reliable hardware response

---

8.4 Validation Criteria

- Sensor readings match physical soil moisture states within reasonable accuracy margins.
- Environmental sensors provide consistent temperature and humidity data.
- System triggers alerts promptly when soil moisture falls below threshold.
- Live data is reflected correctly and updated on the Blynk dashboard with minimal latency.
- System sustains Wi-Fi connectivity and maintains stable communication over extended periods.

The system passed all tests and met validation criteria, confirming it is dependable and effective for smart irrigation assistance.

---

9) Conclusion

This IoT-based soil moisture monitoring and irrigation assistant project demonstrates an effective integration of hardware sensors, microcontroller processing, and cloud-based mobile interfacing for smart plant care. The system reliably monitors soil moisture, environmental temperature, and humidity in real time, offering timely alerts and remote control through the Blynk app to optimize irrigation schedules, conserve water, and enhance plant health.

The pilot deployment confirmed the system's practicality in small garden setups. It provided valuable insights into soil moisture fluctuations, enabled responsive watering actions, and reduced both over-watering and under-watering risks.

The modular design allows easy scaling to larger or multiple zones and future integration with weather forecasting or AI analytics. Overall, the project offers a low-cost, user-friendly, and environmentally beneficial solution that meets the growing need for smart agriculture and water management technologies.

Its deployment in a controlled pilot environment validated both hardware robustness and software reliability, establishing a strong foundation for extended implementations in diverse agricultural and horticultural settings.
